

ABSTRACT OF THE DISCLOSURE

A fluid valve includes a base body having a fluid intake, a fluid outlet and a valve accommodation chamber formed between the fluid intake and fluid outlet, a cylindrical valve accommodated movably in the valve accommodation chamber, and a driving portion for moving the cylindrical valve in a direction for adjusting the opening degree of the cylindrical valve. The cylindrical valve is moved by the driving portion so as to change flow path areas of the first valve second valve flow paths thereby changing the flow rate flowing through the inner peripheral flow path.
